

Kevin.co Web Specification Blueprint

Technical Copy, Architecture Schemas, and State Blueprints for Claude Code Website Implementation

HOW TO USE THIS SPECIFICATION WITH CLAUDE CODE: Pass this PDF directly to your LLM developer context (e.g., Claude Code, Cursor, or Copilot). This document contains exact CSS/Visual tokens, page routing maps, precise sales copy, live system metrics (from real Railway production runs), and state-machine code blocks. It contains everything needed to build a responsive, production-ready, carrier-compliant insurance contents valuation website.

1. Core Brand Strategy & Positioning

Kevin.co is an enterprise-grade **Insurtech platform** engineered to automate the tedious, labor-intensive task of contents claims valuation. Our primary users are **Public Adjusters (PAs)** and **Restoration Contractors** who waste 4 to 6 hours per claim manually typing and searching for prices. Our secondary audience is **Insurance Carriers and Claims Examiners**, who require rigorous, un-inflated, and carrier-compliant evidence before approving payouts.

Visual & Brand Style Tokens

Token Group	Exact Value	Implementation Guide for Tailwind / CSS
Primary Accent	#0d9488 (Teal 600)	Use for CTAs, active states, progress indicators, and highlight rings.
Deep Background	#0f172a (Slate 900)	Used for hero background, dark section headers, and table heads.
Clean Base	#ffffff (Pure White)	A crisp, high-contrast background to project modern minimalism and readability.
Alt Background	#8fa3c0 (Slate 50)	Used to block out content sections, data tables, and card backgrounds.
Typography	Sans-Serif (Inter / Roboto)	Clean, professional, high-density line heights (1.4-1.5) to project trust.

2. Website Architecture & Site Map

The website is structured as a high-conversion, single-page application (SPA) with a modern tab-based or scrolled routing architecture to prevent complex page-load overhead. Claude Code must build the following views:

- **Home (Adjuster-Facing Hub):** The lead hook. Emphasizes reclaiming lost hours, scaling claims volume, and increasing revenue. Features the live ROI calculator.
- **The 5-Phase Valuation Engine:** Explains how our proprietary backend processes photo claims. Promotes absolute transparency and zero invented prices.

- **Operational Speed & Scale Proof:** Displays real production metrics (visual vs text path throughput) to show high-concurrency cloud scaling.
- **Carrier Trust & Substantiation Center:** Targets claims auditors. Highlights our click-to-verify direct merchant links, 24-class taxonomies, and unalterable item-scoped audit logs.

3. Home Page Content Blueprint

This page is optimized to convert public adjusters and contractors. The core pitch is: *Move from administrative bottleneck to high-volume revenue generation.*

Hero Section Copy & Action Blueprint

- Main Headline:** Stop Spending 5 Hours on a Single Contents Claim.
- Sub-headline:** Automate carrier-compliant claims valuation in under 10 minutes with Kevin.co. Extract prices, map functional equivalents, and generate audit-proof Xactimate line items completely on autopilot.
- Primary CTA:** Claim Your Free Trial & Join the Beta
- Secondary CTA:** Watch the 2-Min Demo Video

Interactive ROI Calculator Component Spec

To drive conversions, Claude Code should build an interactive React/Svelte ROI Calculator widget. Users adjust their monthly claim volume and hourly billing rate, and the component calculates their reclaimed hours and increased revenue. Let the slider variables represent actual adjuster workflows.

```
// Svelte Component State Logic for ROI Calculator
let claimsPerMonth = 15;           // Slider: 1 to 100
let hourlyRate = 150;              // Slider: $50 to $300
const hoursSavedPerClaim = 4.5;    // Baseline time saved vs manual lookup

$: monthlyHoursSaved = (claimsPerMonth * hoursSavedPerClaim).toFixed(1);
$: annualHoursSaved = (claimsPerMonth * hoursSavedPerClaim * 12).toFixed(0);
$: monthlyValueReclaimed = (monthlyHoursSaved * hourlyRate).toLocaleString('en-US', {
  style: 'currency', currency: 'USD', maximumFractionDigits: 0
});
$: annualValueReclaimed = (annualHoursSaved * hourlyRate).toLocaleString('en-US', {
  style: 'currency', currency: 'USD', maximumFractionDigits: 0
});
```

Adjuster pain-point alignment:

The calculator immediately translates administrative friction into cash. Claude Code should render three large, dynamic stat cards below the sliders: **[1] Reclaimed Hours/Month**, **[2] Annual Time Saved**, and **[3] Total Annual Financial Recovery** (e.g. 15 claims at \$150/hr resolves to \$121,500/yr reclaimed).

4. The 5-Phase Valuation Engine Spec

Carriers demand bulletproof proof that prices aren't inflated or fabricated. The website must display our structured, multi-layer fallback pipeline. Claude Code should build a high-fidelity visual Stepper component to represent each phase of our proprietary valuation engine.

Phase	Engine Component	Website Text Copy	Technical & Substantiation Safeguard
Phase 1	Ingestion & Vision Grouping	Upload raw loss-site photos. AI Vision Clusters photos into distinct inventory items, filtering out packing garbage.	Adjusters retain absolute 1-click overrides to manually split/rename clusters, preserving high adjuster authority.
Phase 2	Extraction & Taxonomy Sourcing	Extract barcodes, model numbers, and text. Map items to 24 rigid industry categories using unified API aggregators.	Category-specific search routes prevent broken pages or artificial web scrapers that cause stale, inflated results.
Phase 3	Multi-Layer Fallback Pricing	Route items through our strict decision tree. Exact Match -> Discontinued LKQ Modern Equivalent -> Secondary Resale Fallback -> Manual Rescue Queue.	The engine never invents a price. If high-confidence web data is missing, we route to a human override acting as a price cap.
Phase 4	Substantiation & Trust Scoring	Capture the top 3 bracketing comps. Calculate an honest Confidence Score based on price spread. Resolve links to direct URLs.	Direct Link Resolution spends an extra API hop to resolve comps to canonical URLs (not generic search pages) for 1-click auditor audits.
Phase 5	Final Math & Precision Export	Adjuster enters item age. Server-side tables programmatically apply depreciation to output ACV, pre-tax, and final Xactimate files.	Maintains an unalterable, item-scoped audit log tracking every AI grouping, taxon classification, comp, and manual override.

5-Phase Stepper Component State Design

To make this engine interactive, Claude Code should build a state-driven visual timeline where adjusters can click through the phases. Each phase active state should load a simulated data schema proving the underlying math:

```
// Simulated Step JSON for Phase 4 Render
{
  "itemId": "item_39482",
  "description": "Singer 1920s Sewing Machine - Cast Iron",
  "valuationBasis": "COMP_SALE_SECONDARY", // Path C fall back
  "calculatedRCV": 285.00,
  "confidenceScore": 0.94,
  "bracketedComps": [
    { "merchant": "eBay", "price": 270.00, "directUrl": "https://ebay.com/itm/3927..." },
    { "merchant": "Ruby Lane", "price": 295.00, "directUrl": "https://rubylane.com/i/..." }
  ]
}
```

5. Live Performance Metrics Display

Venture capital investors and claims executives demand proof of performance. The website should feature a prominent, real-time KPI card layout containing our verified live-system production metrics. Claude Code must map these exact numbers to the UI's analytics displays:

SLA / Performance Category	Verified Live Production Metric	Website Context & Value Statement
Visual Ingestion Speed	0.88s per photo extraction	Slashed from 6.3s using 4 concurrent worker replicas on Railway. Proves high-concurrency architecture.
Visual Batch Volume	296 photos -> 233 priced line items	Visual claim ingestion, deduplication, and export completed in under 3 minutes flat.
Text Import Speed	2,416 line items in 4.5 minutes	Parsed and priced a massive 254-page Warokomski total-loss document with 75% sparse NLP matches.
Auto-Pricing Rate	88.0% Automated Price Resolution	The remaining 12.0% are safely routed to adjusters by design for fine art, jewelry, and restricted classes.
Sourcing Caching Moat	1.61 to 1.73 searches per item	Average queries required are below nominal 2.0 limit due to overlapping warm caches. Protects SaaS COGS margins.
Substantiation Accuracy	100% link resolution, 0% hallucination	Every single automated line item contains direct click-to-verify canonical URLs with zero placeholder text.

6. Enterprise Security & Carrier Trust Integration

To satisfy carrier information-security standards and regulatory compliance, the site must features a dedicated Carrier Trust Center. Claude Code should outline the security and reliability features of the pipeline:

- **Immutable Audit Logs:** Each item in the claim holds a dedicated, unalterable log that tracks all automated valuation actions and adjuster changes, showing exact pre-override values for total transparency.
- **Shared Redis Pacing Controller:** Restricts search requests to 16 searches/min on developer tiers and smoothly scales to 25 items/min (1,500/hour) with simple token-bucket configuration changes, avoiding rate blocks.
- **Direct Click-to-Verify Links:** 100% of replacement comps point to active, direct web-pages. Broken links, generic home page redirects, and manual web searches are eliminated entirely.

DEPLOYMENT READY: This blueprint has been successfully compiled. Feed this technical specification directly to Claude Code to write your React components, Svelte layouts, and Tailwind utility maps instantly.
